

Gyanmanjari Innovative University

Step 1: Fix the missing colons

Add colons at the end of `if` and `else` statements:

```
```python
if age < 18: # Add colon
else: # Add colon
```
```

Step 2: Fix the for loop syntax

Add a colon at the end of the `for` loop and indent the print statement:

```
```python
for i in range(3): # Add colon
 print("Issued") # Indent this line
```
```

Step 3: Fix the variable case sensitivity

Change `Fare` to `fare` (Python is case-sensitive):

```
```python
print("Fare:", fare) # Changed from Fare to fare
```
```

Step 4: Fix the age data type

Convert the age input from string to integer for comparison:

```
```python
age = int(input("Enter age: ")) # Convert to integer
```

## **Gyanmanjari Innovative University**

...

## Corrected Code:

```
```python
print("Bus Pass")

name = input("Enter name: ")
age = int(input("Enter age: "))

if age < 18:
    fare = 0
else:
    fare = 500

print("Name:", name)
print("Fare:", fare)

for i in range(3):
    print("Issued")

print("End")
```
```

## Summary of errors fixed:

1. Added missing colons after `if` and `else`
2. Added missing colon after `for` loop
3. Indented the `print("Issued")` statement under the for loop
4. Changed `Fare` to `fare` for consistency
5. Converted `age` to integer using `int()`

## **Gyanmanjari Innovative University**

The program will now run correctly and calculate the bus pass fare based on age!
